

Torsional vibrations and torsion modulus

LEP 1.3.30

Related topics

Shear modulus, angular velocity, torque, moment of inertia, angular restoring torque, G-modulus, modulus of elasticity.

Principle and task

Bars of various materials will be exciting into torsional vibration. The relationship between the vibration period and the geometrical dimensions of the bars will be derived and the specific shear modulus for the material determined.

Equipment

• •		
Torsion apparatus	02421.00	1
Torsion rod, steel, I 500 mm, d 2mm	02421.01	1
Torsion rod, Al, I 500 mm, d 2 mm	02421.02	1
Torsion rod, Al, I 400 mm, d 2 mm	02421.03	1
Torsion rod, Al, I 300 mm, d 2 mm	02421.04	1
Torsion rod, Al, I 500 mm, d 3 mm	02421.05	1
Torsion rod, Al, I 500 mm, d 4 mm	02421.06	1
Torsion rod, brass, I 500 mm, d 2 mm	02421.07	1
Torsion rod, Cu, I 500 mm, d 2 mm	02421.08	1
Spring Balance 1 N	03060.01	1
Spring balance 2, 5 N	03060.02	1
Stopwatch, digital, 1/100 sec.	03071.01	1
Sliding weight	03929.00	2
Support base -PASS-	02005.55	1
Support rod -PASS-, square, I 250 mm	02025.55	1
Support rod -PASS-, square, I 630 mm	02027.55	1
Right angle clamp -PASS-	02040.55	2

Fig.1: Experimental set-up for determining the torsion modulus of various bars.

Problems

- 1. Static determination of the torsion modulus of a bar.
- Determination of the moment of inertia of the rod and weights fixed to the bar, from the vibration period.
- 3. Determination of the dependence of the vibration period on the length and thickness of the bars.
- Determination of the shear modulus of steel, copper, aluminium and brass.

Set-up and procedure

The experimental set-up is arranged as shown in Fig. 1. Care should be taken that the torsion bars are perpendicular to the beam. For the static determination of the torsion modulus, the spring balance acts on the beam at r = 0.15 cm. The spring balance and lever arm form a right angle. It is recommended that the steel bar, 0.5 m long, 0.002 m dia., is used for this experiment, since it is distinguished by a wide elastic range.

The steel bar is also preferable for determining the moment of inertia of the rod with the two masses arranged symmetrically (longer vibration period).

The bars must not be deflected so far that the zero-point is shifted (yield point, hysteresis) or that the bar rotates in the upper clamping sleeve.

Theory and evaluation

If a body is regarded as a continuum, and if $\vec{r_o}$ and \vec{r} denote the position vector of a point p in the undeformed and deformed states of the body, then for small displacement vectors

$$\overrightarrow{u} = \overrightarrow{r} - \overrightarrow{r_0} \equiv (u_1, u_2, u_3)$$

and the deformation tensor d is:

$$d_{ik} = \frac{\partial u_i}{\partial x_k} + \frac{\partial u_k}{\partial x_i} \ .$$

The forces $d\vec{F}$, which act on a volume element of the body, the edges of the element being cut parallel to the coordinate planes, are described by the stress tensor $\hat{\tau}$. To each area element dA, characterised by the unit vector \vec{e} in the direction of the normal, there is assigned the stress \vec{p} :

$$\vec{p} = \frac{d\vec{F}}{dA}$$

$$\vec{p} = \vec{e} \cdot \hat{\tau}$$

Hooke's law provides the relationship between \hat{d} and $\hat{\tau}$:

$$\tau_{ik} = \sum_{l,m} c_{ik}^{lm} d_{lm}$$

The tensor \hat{c} is symmetrical for an elastic body, so that only 21 of the 81 components remain. For isotropic elastic bodies, this number is further reduced to 2 values, namely the modulus of elasticity E and the shear modulus G or the Poisson's ratio μ :

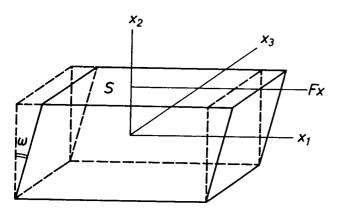

$$\tau_{11} = \frac{E}{1+u}$$

$$\left\{d_{11} + \frac{\mu}{1-2\mu} \left(d_{11} + d_{22} + d_{33}\right)\right\}$$

Torsional vibrations and torsion modulus

Fig. 2: Force and resultant deformation $F_X = G \cdot S \cdot \omega$.

$$\tau_{12} = G d_{12} = \frac{1}{2} \frac{E}{1+\mu} d_{12}$$
 (1)

and analogously for τ_{22} , τ_{33} , τ_{13} , τ_{23} .

Using the notations of Figs. 2 and 3, equation (1) can be written:

$$dF_x = G \cdot \omega \cdot dS = G \cdot \frac{r\varphi}{L} \cdot rdr \cdot d\alpha$$
.

From this, the total torque a ring is obtained

$$dT_Z = \int_{0}^{2\pi} dF_x \cdot r = \frac{2\pi G r^3 \phi dr}{L}$$

and from this the total torque

$$T_Z = \int\limits_{O}^{R} dT_Z = \frac{\pi}{2} \cdot G \cdot \phi \cdot \frac{\mathsf{R}^4}{L}.$$

From the definition of the angular restoring torque or torsion modulus D_T ,

$$T_{\mathcal{T}} = D_{\mathcal{T}} \cdot \Phi \tag{2}$$

one obtains

$$D_T = \frac{\pi}{2} \cdot \frac{\mathsf{R}^4}{L} \cdot \mathsf{G} \; .$$

From Newton's basic equation for rotary motion

$$\overrightarrow{T} = \frac{d}{dt} \overrightarrow{L}$$
.

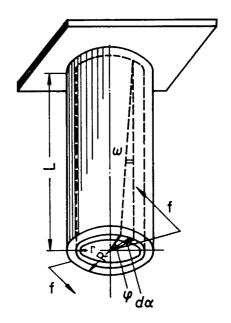

– were the angular momentum \vec{L} is related to the angular velocity $\vec{\omega}$ and the inertia tensor \hat{I} in accordance with

$$\vec{L} = \hat{l} \cdot \vec{\omega}$$

- and from (2), one obtains

$$\frac{d^2\phi}{dt^2} + \frac{D_T}{I_Z}\phi = o.$$

Fig. 3: Torsion in a bar.

The period of this vibration is

$$T = 2\pi \sqrt{\frac{I_Z}{D_T}} \tag{3}$$

or

$$T = 2\pi \sqrt{I_Z \cdot \frac{2}{\pi} \cdot \frac{L}{G} R^{-2}} \tag{4}$$

In Problem1, D_T is determined in accordance with (2).

Torsional vibrations and torsion modulus

LEP 1.3.30

Fig. 5: Vibration period of a torsion bar as a function of its length.

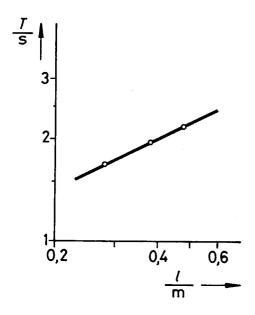

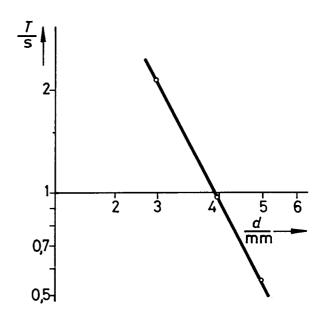

Fig. 6: Vibration period of a torsion bar as a function of its diameter.

From the regression line to the measured values of Fig. 4 with the linear statement

$$Y = A + BX$$
,

the slope

$$B = 0.238 \text{ Nm/rad}$$
 (see (2))

is obtained.

From (3), the moment of inertia of the vibrating bars and masses is determined for the same torsion bar:

$$I_7 = 9.24 \cdot 10^{-3} \text{ kgm}^2$$
.

Figures 5 and 6 show the relationship between the vibration period and the length and diameter of the aluminium bars.

From the regression line to the measured values of Fig. 5 with the exponential statement

$$Y = A \cdot X^B$$

the exponent

$$B = 0.49 \pm 0.01$$
 (see 4))

is obtained.

From the regression line to the measured values of Fig. 6, with the exponential statement

$$Y = A \cdot X^B$$

the exponent

$$B = -1.99 \pm 0.01$$
 (see (4))

is obtained.

Finally, the shear modulus G is determined from (4) for Cu, Al, steel and brass.

$$G_{Cu}$$
 = 38 · 10⁹ N/m²rad
 G_{Al} = 24 · 10⁹ N/m²rad
 G_{Steel} = 76 · 10⁹ N/m²rad
 G_{Rrace} = 32 · 10⁹ N/m²rad
