

PHY3004: Nuclear and Particle Physics

Marcel Merk, Jacco de Vries

The Standard Model

Introducing the lecturers

Lecturers:

Marcel Merk

Jacco de Vries

Tutors:

Lex Greeven

Robbert Geertsema

Research (theoretical):

- Why a *matter-vs-antimatter asymmetry* in nature?
- Why do we have *three generations* of particles?

Research (experimental):

- Detector technology at the *Large Hadron Collider*.
- *Measurements of CP violation rare decays*

The Goal of these Lectures

- A first course in particle physics theory and experiment
 - Solid preparation for a master on particle physics
- Various topics introduced
 - Cannot go to “deep” in each topic
 - Aim is to give you a “feel” for the subject
 - Quite some mathematics later on, but focus on the concept if you find the math difficult!
- Follow-up possibilities in master education:
 - Theoretical Particle Physics: Field theory courses
 - Theoretical and Experimental Particle Physics: Advanced particle physics courses
 - Experimental Particle Physics: Detection techniques for particles

Particle Physics – contents of the course

- Week 1: “Particles”
 - Nuclear Physics and Particle Physics
- Week 2: “Forces”
 - Electromagnetism, Weak force, Strong force
- Week 3: “Waves”
 - Wave Equations
 - Schrodinger, Klein – Gordon, Dirac, Photon-field
 - Lagrange Hamilton mechanics and Gauge Invariance
- Week 4: “Symmetries”
 - The Standard Model gauge symmetry
 - Discrete symmetries
 - Symmetry breaking: the Higgs Mechanism
- Week 5: “Scattering”
 - Scattering Theory
 - Feynman Calculus
- Week 6: “Experiments”
 - Experimental techniques, LHC detectors

- Week 1 – 5:
 - Homework exercises 1 exam “bonus”
- Week 6: Research Project
 - Written paper 5 points
 - Presentation 5 points
- Week 7: Exam 10 points

Literature belonging to the lectures:

- Griffiths: “Introduction to Elementary Particles”
- Lecture notes PP1 master course from Nikhef:
<https://www.nikhef.nl/~i93/Master/PP1/2017/Lectures/Lecture2017.pdf>

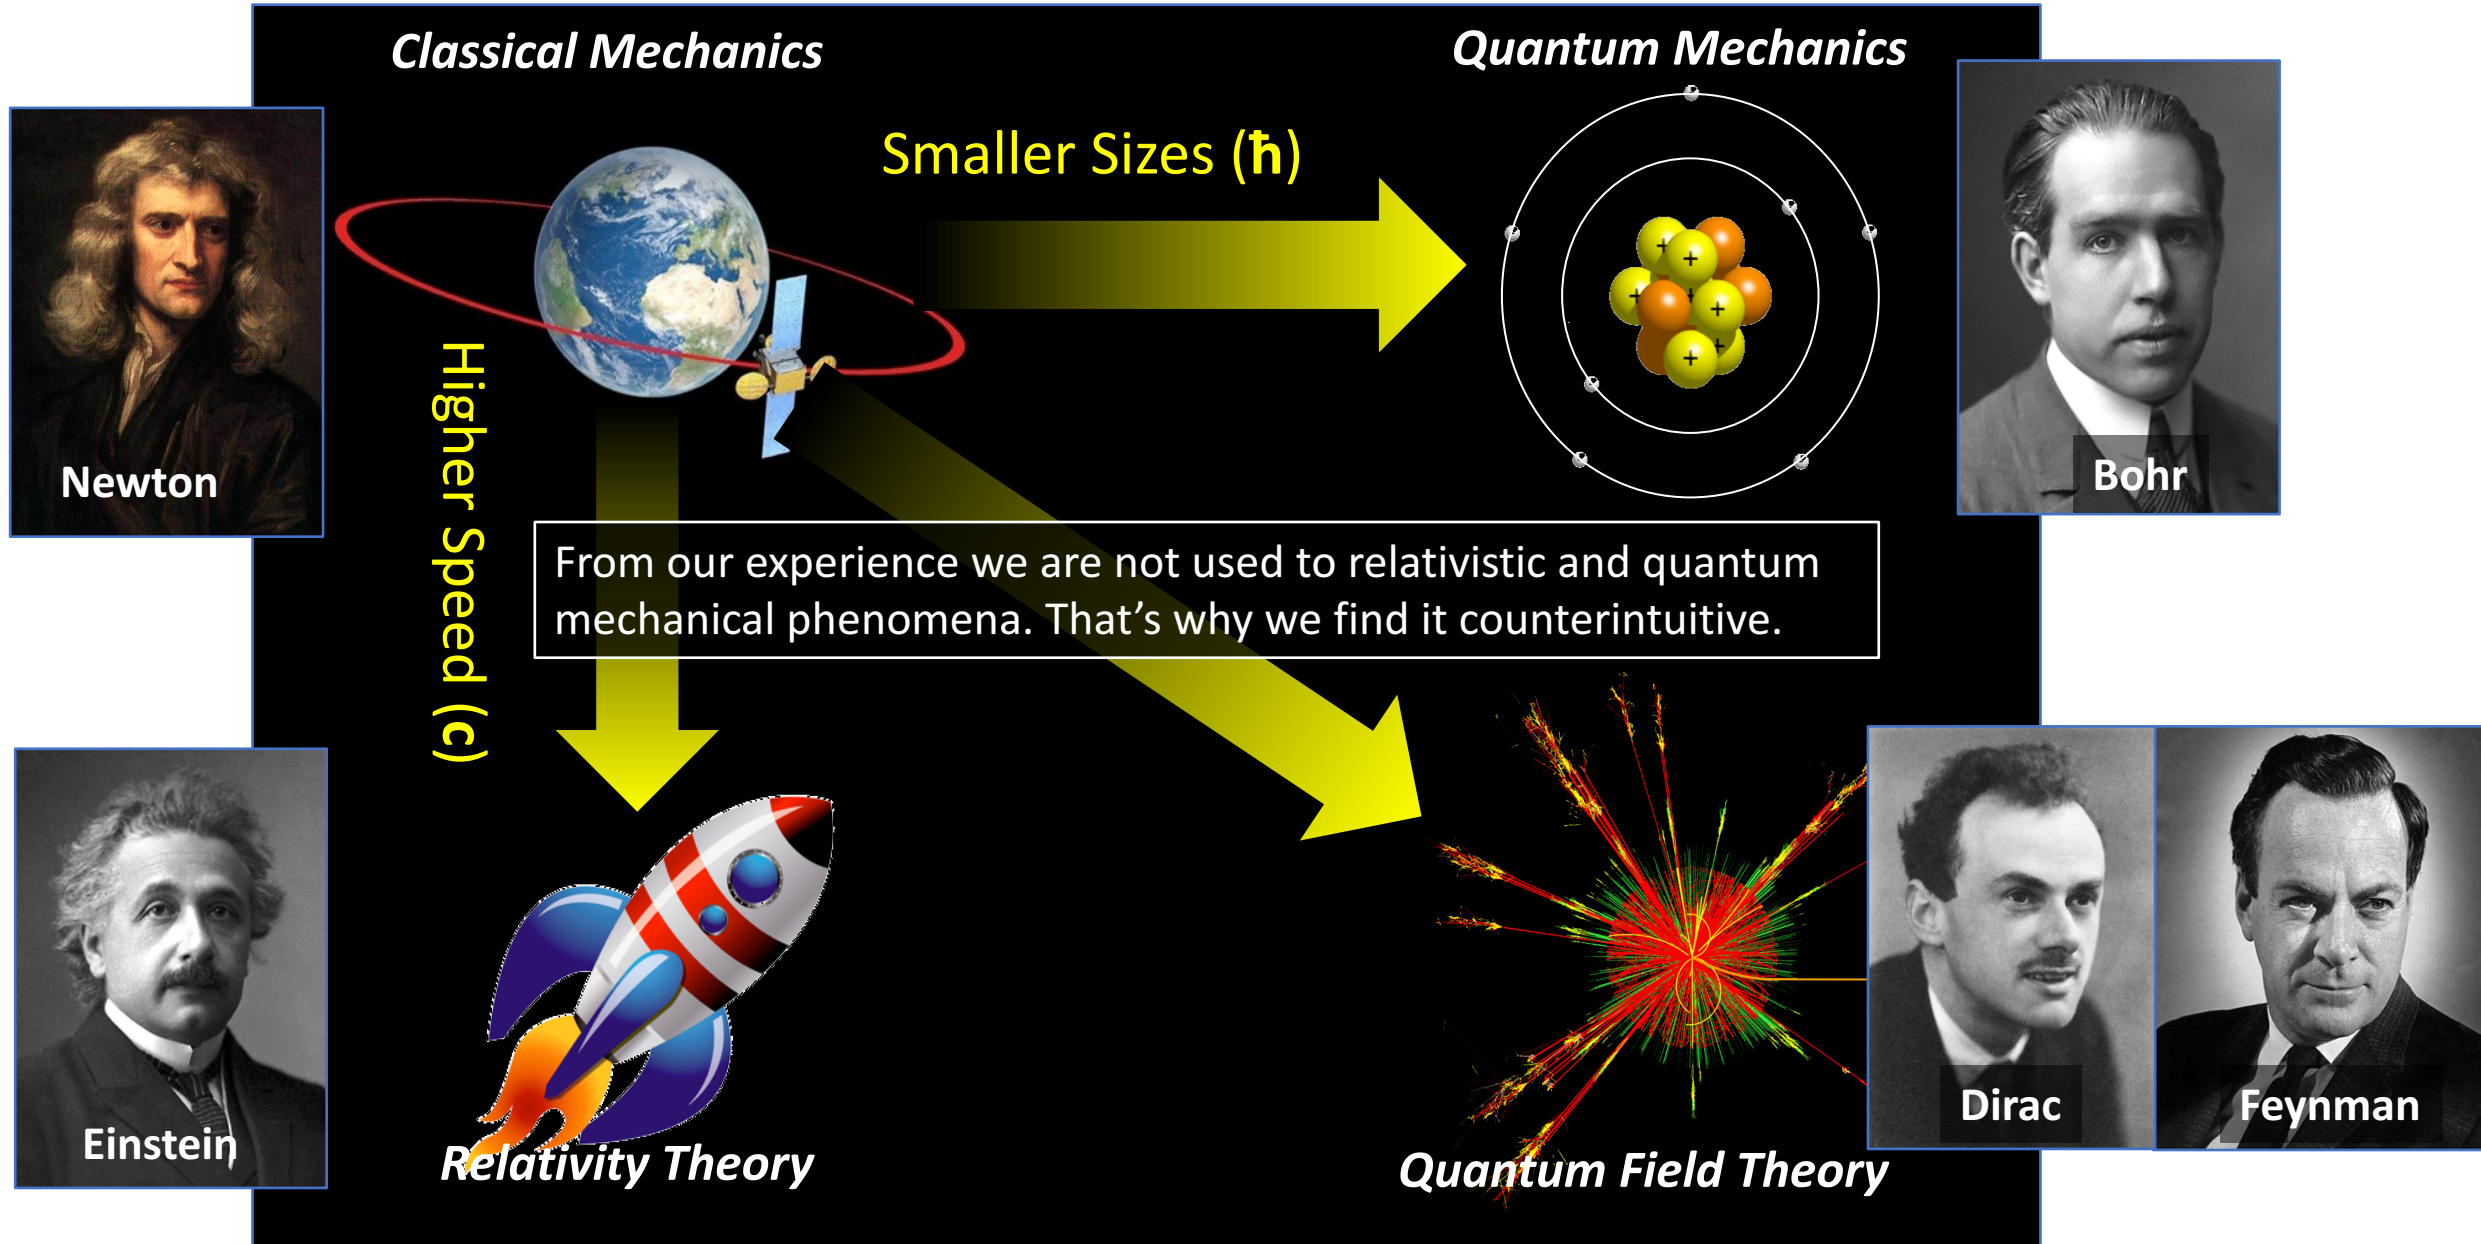

Other good books:

- Mark Thomson: “Modern Particle Physics”
- Halzen and Martin: “Quarks & Leptons: An Introductory Course in Modern Particle Physics”
- Aitchison and Hey: “Gauge Theories in Particle Physics” – 2 volumes

Lecture 1: “Particles”

Tools: Relativity and Quantum Mechanics

How does nature behave in extreme conditions?

← Experimentally tested domain of the Standard Model

Big Bang

↑ ↑
← Do we understand the physics also here? →

How does nature behave in extreme conditions?

← Experimentally tested domain of the Standard Model

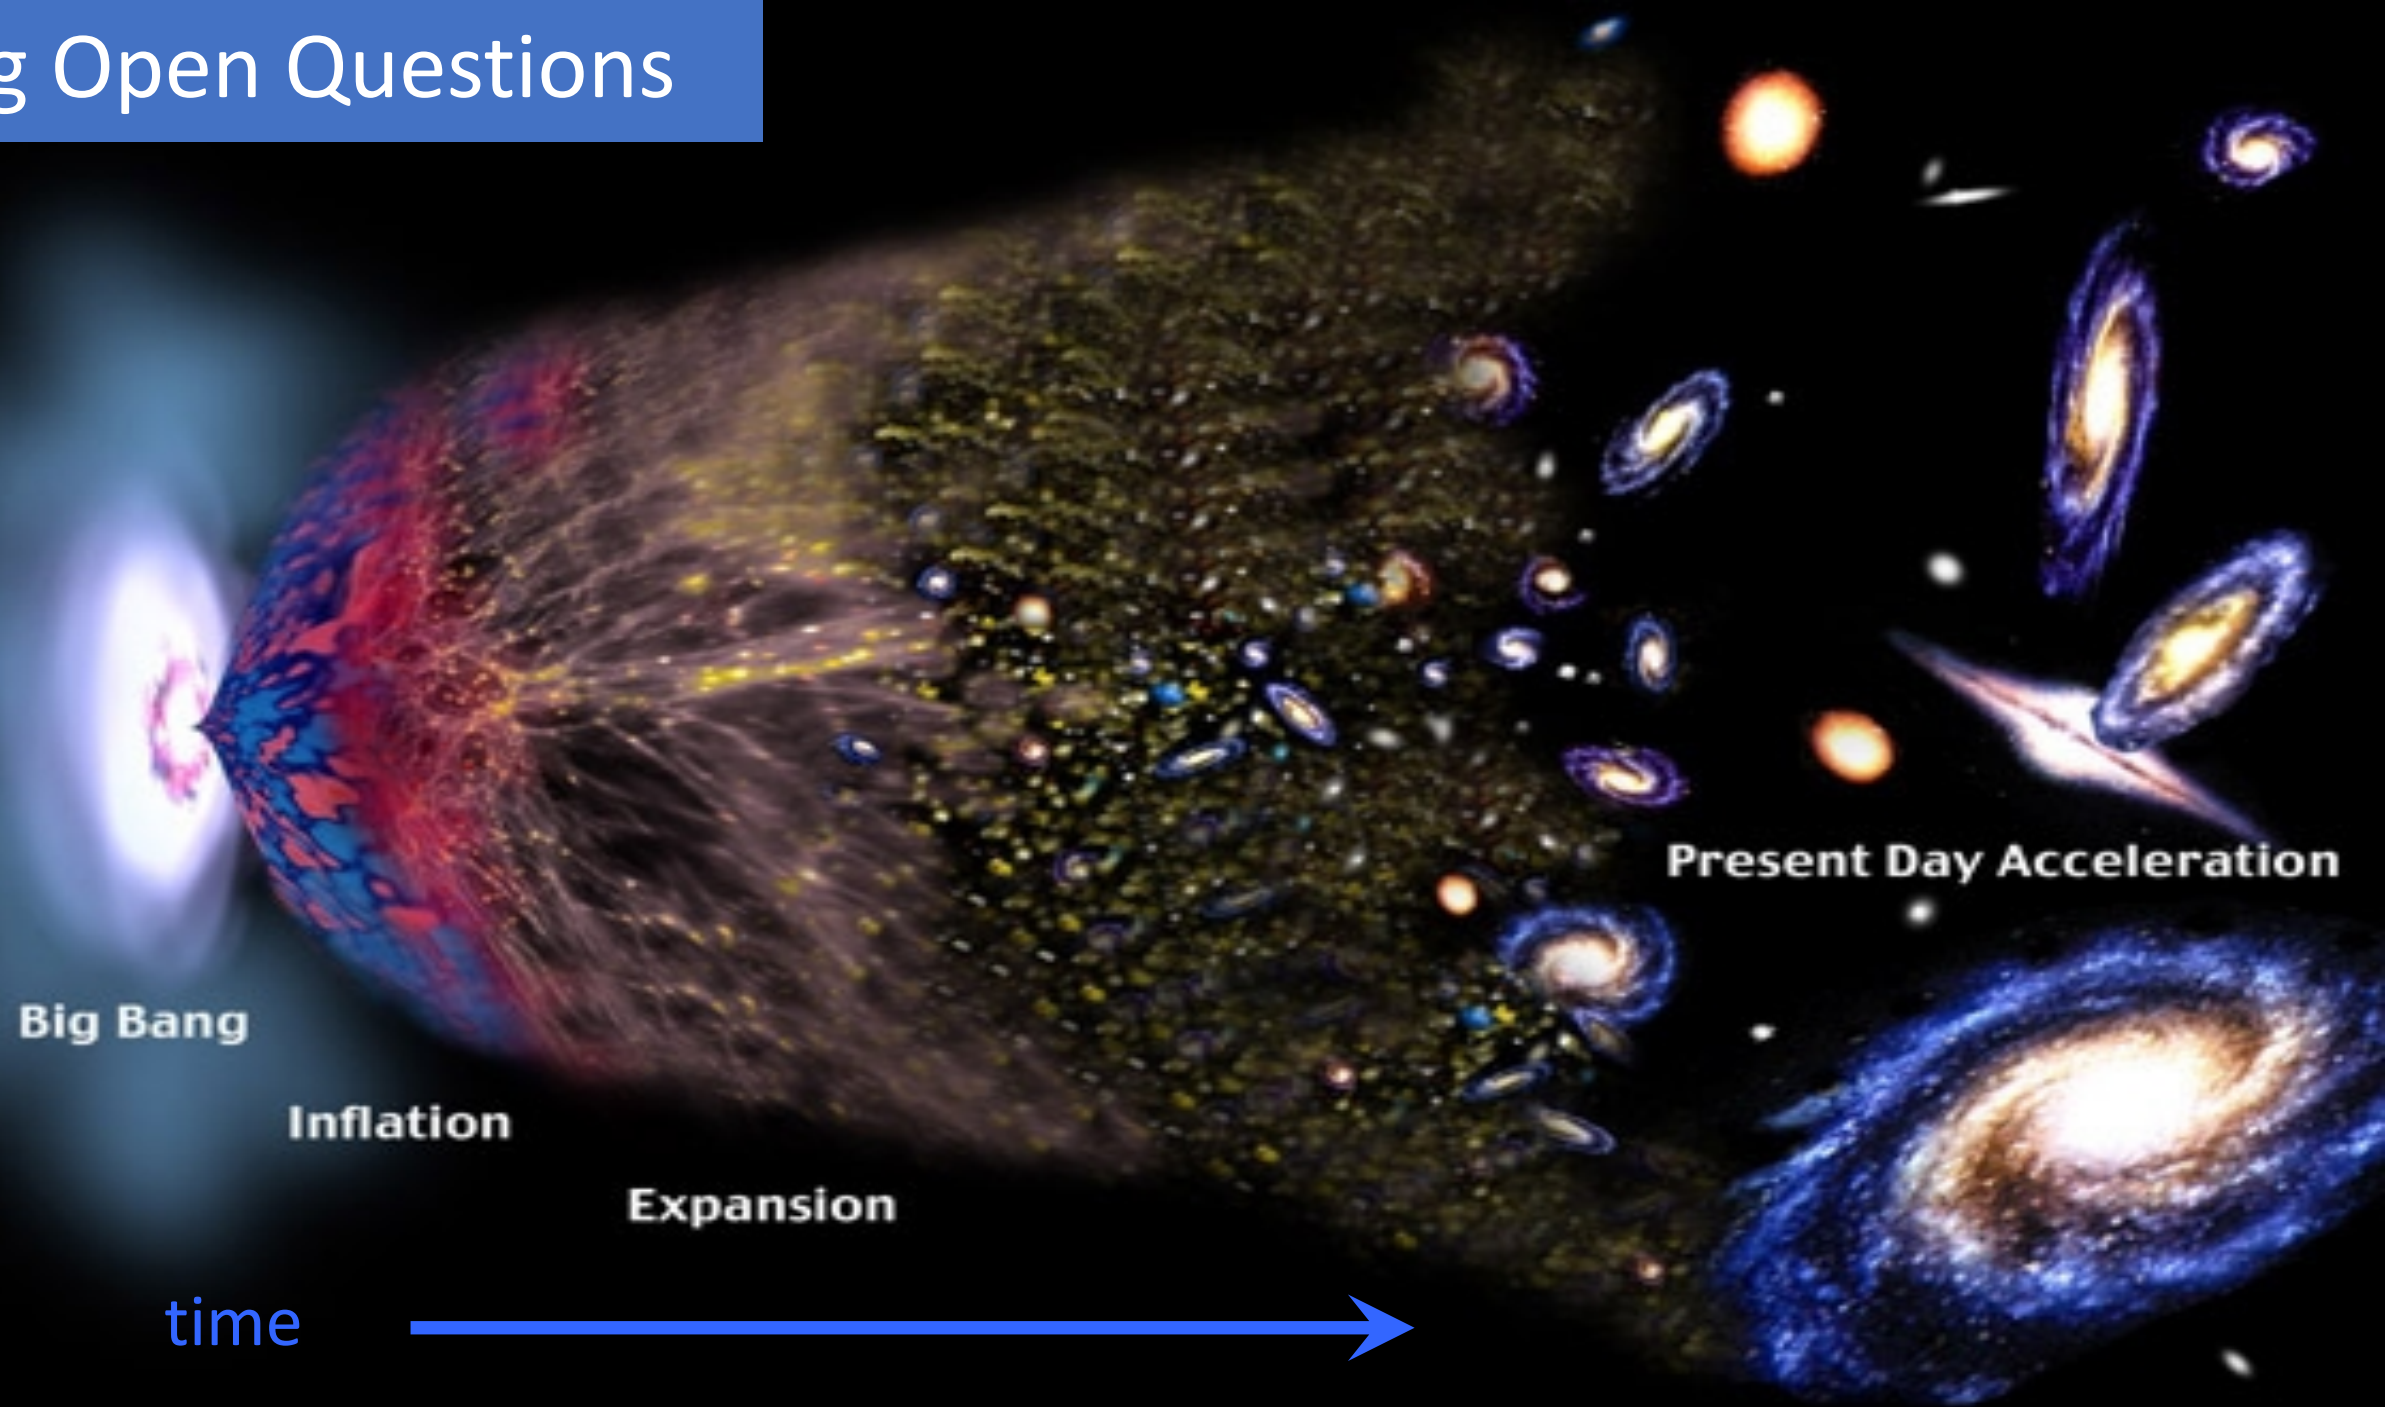

The Large Hadron Collider

Big Bang

Big Open Questions

Big Open Questions

1. Which are the elementary **building blocks** of matter?
 2. Which **forces** exist in nature and what are their essential differences?
 3. Is **empty space** ('the vacuum') truly empty?
 4. Can we explain the existence of **our universe** from the *big bang* using the known laws of nature?
- *Wanted: a consistent theory that can answer these questions*

Present Day Acceleration

Big Bang

Inflation

Expansion

Lecture 1: Particles

Part 1

The Structure of Matter (Nuclear Physics)

Building Blocks of Matter

Stable Matter on Earth

The Lego blocks of nature

Exercise-1: Which mental picture do you make of an atom?

Classic picture of the atom

- Does something “move”?
- How empty is it?
- How does an electron “exist”?

➔ Consider QM interpretations

Exercise-1: Which mental picture do you make of an atom?

Classic picture of the atom

- Does something “move”?
- How empty is it?
- How does an electron “exist”?

➔ Consider QM interpretations

Discovery of the Electron

Griffiths §1.1

- JJ Thomson (1897):
Cathode rays are bent by electric and magnetic field
 - Charged particles

1. Compensate Electric and magnetic deflection:

$$F_E = F_B$$

$$qE = qvB ; v = E/B$$

2. Only B-field, cycle orbit:

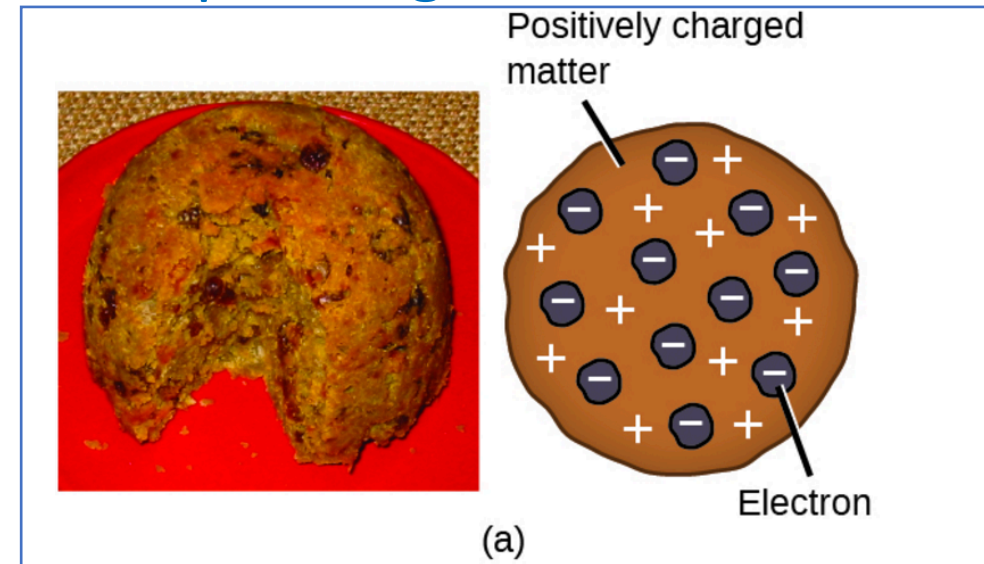

$$F_c = F_B$$

$$\frac{mv^2}{r} = qvB$$

$$\frac{q}{m} = \frac{E}{rB^2}$$

Electrons are much lighter than ions of same charge!

- Plum-pudding model of atoms:

- Atom is basically just vacuum:
 - Atom size: $\sim 10^{-10} m$
 - Nucleus size: $\sim 10^{-15} m$

- Rutherford (1911)
 - α -particles at gold target
 - Most particles pass undisturbed, few have a "hard" collision
 - Atom has substructure: small heavy nucleus

Example Rutherford scattering

Griffiths §1.1

- Rutherford scattering

- Formula derivation:

- https://en.wikipedia.org/wiki/Rutherford_scattering

- → not required

Example Rutherford scattering

Griffiths §1.1

- Rutherford scattering

- Formula derivation:

- https://en.wikipedia.org/wiki/Rutherford_scattering

- → not required

$$b = \frac{Z_1 Z_2 e^2}{4\pi\epsilon_0 m v^2} \cot \frac{\theta}{2}$$

$$\frac{d\sigma}{d\Omega} = \frac{Z_1 Z_2 \alpha^2}{16 E_{kin}^2 \sin^2(\theta/2)}$$

- Niels Bohr, 1914:
 - Calculate atomic energy levels using semi classical method

de Broglie: $\lambda = h / p$

$$\begin{aligned} L &= r p \\ L &= r h / \lambda \\ L &= r n h / (2 \pi r) \\ L &= n h / (2 \pi) = n \hbar \end{aligned}$$

- Balmer spectrum of visible wavelengths in hydrogen:

- Niels Bohr, 1914:
 - Calculate atomic energy levels using semi classical method

Exercise-2 “Pub Quizz”:

- 1: How come an atom is stable?
- 2: What hits each other when you clap your hands?
- 3: Why does a hydrogen electron not interact with the proton?

?

Nuclear Physics

- Nuclei include protons, p
 - Masses of nuclei studies in chemistry (Avogadro)
 - Hydrogen = 1 proton: $M_H = 1 \text{ GeV}/c^2 = 200 M_e$
- Study q/m of nuclei:
 - Masses of nuclei do not scale with charge, but with $A \approx 2 \times Z$
 - A = mass number, Z = atomic number = nucleus charge
 - What keeps heavy nuclei together?
- Chadwick 1932: Discovery of neutron, n
 - Neutron has almost same mass as proton
 - Neutrons act as a glue to nucleons in the nucleus
 - Later we will see it is due to the gluon color force
- Notation: ${}^A_Z\text{MyAtom}$, with $Z = \#p$, $A = \#(p + n)$
 - Isotopes: same $\#p$, different $\#n$

Electric Force vs Nuclear Force

- Electric Force: inverse square law
 - Generated by exchange of massless photon quanta
- Nuclear Force
 - must be (much) stronger than electric force in the nucleus
 - must be (much) weaker than electric force outside the nucleus
- Pauli exclusion principle: Two fermions (protons, neutrons) cannot be at the same position
 - The potential must have a very strong repulsive core at small r
- Potential square well model
 - For protons there is a “Coulomb barrier” V_B
 - Beyond the range R it is negligible
 - With Rutherford scattering the range can be determined
 - $R \propto A^{1/3}$
- Nuclear force generated by exchange of massive pion

Electric Force vs Nuclear Force

- Electric Force: inverse square law
 - Generated by exchange of massless photon
- Nuclear Force
 - must be (much) stronger than electric force in the nucleus
 - must be (much) weaker than electric force outside the nucleus
- Pauli exclusion principle: Two fermions (protons, neutrons) cannot be at the same position
 - The potential must have a very strong repulsive core at small r
- Potential square well model
 - For protons there is a “Coulomb barrier” V_B
 - Beyond the range R it is negligible
 - With Rutherford scattering the range can be determined
 - $R \propto A^{1/3}$
- Nuclear force generated by exchange of massive pion

Yukawa's pion

Griffiths: problem 1.2, PP1 §i.2

- Yukawa (1934) pi-meson gives attractive force between nucleons
- Heisenberg operator uncertainty in QM: $\Delta E \Delta t \geq \frac{\hbar}{2}$
- Translated to popular language:
 - You can violate energy conservation as long as:
 - time is shorter than: $\Delta t \leq \frac{\hbar}{2\Delta E}$ or energy is less than $\Delta E \leq \frac{\hbar}{2\Delta t}$
- Electromagnetic force is transmitted by photon quanta
 - $E = hf = \frac{hc}{\lambda}$ such that: $\Delta t \sim \frac{\lambda}{c}$ and the range $R \sim c\Delta t = \lambda$ is infinite
- Nuclear (“strong”) force is transmitted by massive pions:
 - $E = mc^2$ such that $\Delta t \sim \frac{h}{2mc^2}$ and $R \sim c\Delta t = \frac{h}{2mc}$
 - The heavier the particle, the more difficult to “violate energy conservation”, the shorter the range
- In 1937 a particle with the correct mass was found in cosmic rays, but it did not interact with nuclei!
 - “Who ordered that?” (Isidor Rabi). It was the muon.
- In 1947 the pion was discovered

Exercise-2 : The Yukawa Potential

- The electric force is transmitted by a photon with $m = 0$. The wave equation for a static electric field caused by pointlike charge e is: $\nabla^2 V(r) = 0$ (Laplace equation)
 - a) Show that the Coulomb potential $V(r) = -e^2 \frac{1}{r}$ fulfills this equation.
 - Note that the potential is **spherical symmetric**, ie. use spherical coordinates.
- The nuclear force is transmitted by a pi-meson with $m = m_\pi$. The wave equation for a static nuclear field caused by a pointlike color charge g is: $\nabla^2 U(r) = m^2 U(r)$ (Klein-Gordon equation)
 - b) Show that the Yukawa potential $U(r) = -g^2 \frac{e^{-r/R}}{r}$ fulfills this equation for a certain value of R , the **range** of the force. What is the relation between R and m_π ?
 - Again note that the potential is **spherical symmetric**.
 - This value is between the electron and proton mass, hence the particle was called a pi-meson or pion.
 - c) Calculate the range of the force from Heisenberg's uncertainty relation, using $R = c\Delta t$ and $\Delta E \Delta t \leq \frac{\hbar}{2}$ and $\Delta E = mc^2$.
 - d) The weak force is mediated by W (80 GeV) and Z (91 GeV) bosons. What is the estimated range of the weak force?

The nucleon-nucleon potential

- Woods Saxon Potential, 1954

- $V(r) = -\frac{V_0}{1+\exp\left(\frac{r-R}{a}\right)}$
- Nuclear Radius: $R = 1.25 \text{ fm} \times A^{1/3}$
 A is mass number, $V_0 \approx 50 \text{ MeV}$, $a \approx 0.5 \text{ fm}$

- Many models in 1970 – 1990

- Reid Potential, 1968, (semi-empirical) implements repulsive core:

- $$V_{Reid}(R) = -10.463 \frac{e^{-\mu r}}{\mu r} - 1650.6 \frac{e^{-4\mu r}}{\mu r} + 6482.2 \frac{e^{-7\mu r}}{\mu r}$$

in MeV with $\mu = 0.7 \text{ fm}^{-1}$

- Famous nucleon-nucleon potential is the Nijmegen potential:

- De Swart, Rijken et al., 1980 - 1990
- <https://arxiv.org/pdf/nucl-th/9509024.pdf>

Binding Energy

- The energy of the state inside the potential well is lower than the energy of free particles
- If you “build” a nucleus from free particles energy becomes available: “binding energy”
- This appears by a reduction of mass: the nucleus is lighter than the sum of its components.
- Binding energy: $E = \Delta m c^2$
- $\Delta m = m_{\text{nucleus}} - (N_p M_p + N_n M_n)$
 $= m_{\text{nucleus}} - (Z M_p + (A - Z) M_n) < 0$
 - This holds for all bound systems
 - Hydrogen: $m_p + m_e = m_H + 13.6 \text{ eV}/c^2$
 - Deuterium: $m_p + m_n = M_D + 1.7 \text{ MeV}/c^2$
- ^{56}Fe has the highest binding energy

Nuclear decay (Radioactivity)

- Radioactivity (1896)

Henri Becquerel, Pierre and
Marie Curie:

- Unstable nucleus
- Quantum tunneling process

- Rutherford classification into: alpha, beta, gamma decays
 - alpha and beta decay changes chemical element (Z)

- In nature things decay exponentially:

- Equal probability per unit time:

$$-dN = \lambda N dt$$

$$N(t) = N_0 e^{-\lambda t} = N_0 e^{-t/\tau}$$

- Halflife:

$$N_{1/2} = N_0/2 \rightarrow e^{-t_{1/2}/\tau} = \frac{1}{2} \rightarrow -t_{1/2}/\tau = \ln \frac{1}{2} \rightarrow t_{1/2} = \tau \ln 2$$

alpha decay

- Beta particles stopped by sheet of aluminium
- Gamma particles stopped by layer of lead

Radioactive Elements

- Half-lives vary enormously

- At least one stable element exists
- Slightly radioactive $\tau_{1/2} \sim$ millions of years
- Radioactive: $\tau_{1/2} \sim$ thousands of years
- Highly radioactive: $\tau_{1/2} \sim$ minutes to weeks
- Extremely radioactive: $\tau_{1/2} \sim$ seconds

Extremely radioactive: $\tau_{1/2}$ ~seconds

A scatter plot showing the half-life ($\tau_{1/2}$) of various isotopes as a function of their atomic number (Z). The y-axis represents half-life on a logarithmic scale from 10^{-8} s to 10^{-1} s. The x-axis represents atomic number (Z) from 0 to 100. A diagonal line labeled 'N' (representing N=Z) is shown. Data points are colored by half-life, with a color bar on the right indicating values from 10^{-8} s (dark blue) to 10^{-1} s (light blue). Most data points follow the N=Z line for low Z, then curve upwards and to the right as Z increases, indicating longer half-lives for heavier elements.

Units in Radiation and Tissue

Inform yourself on doses related to Chernobyl and Fukushima.

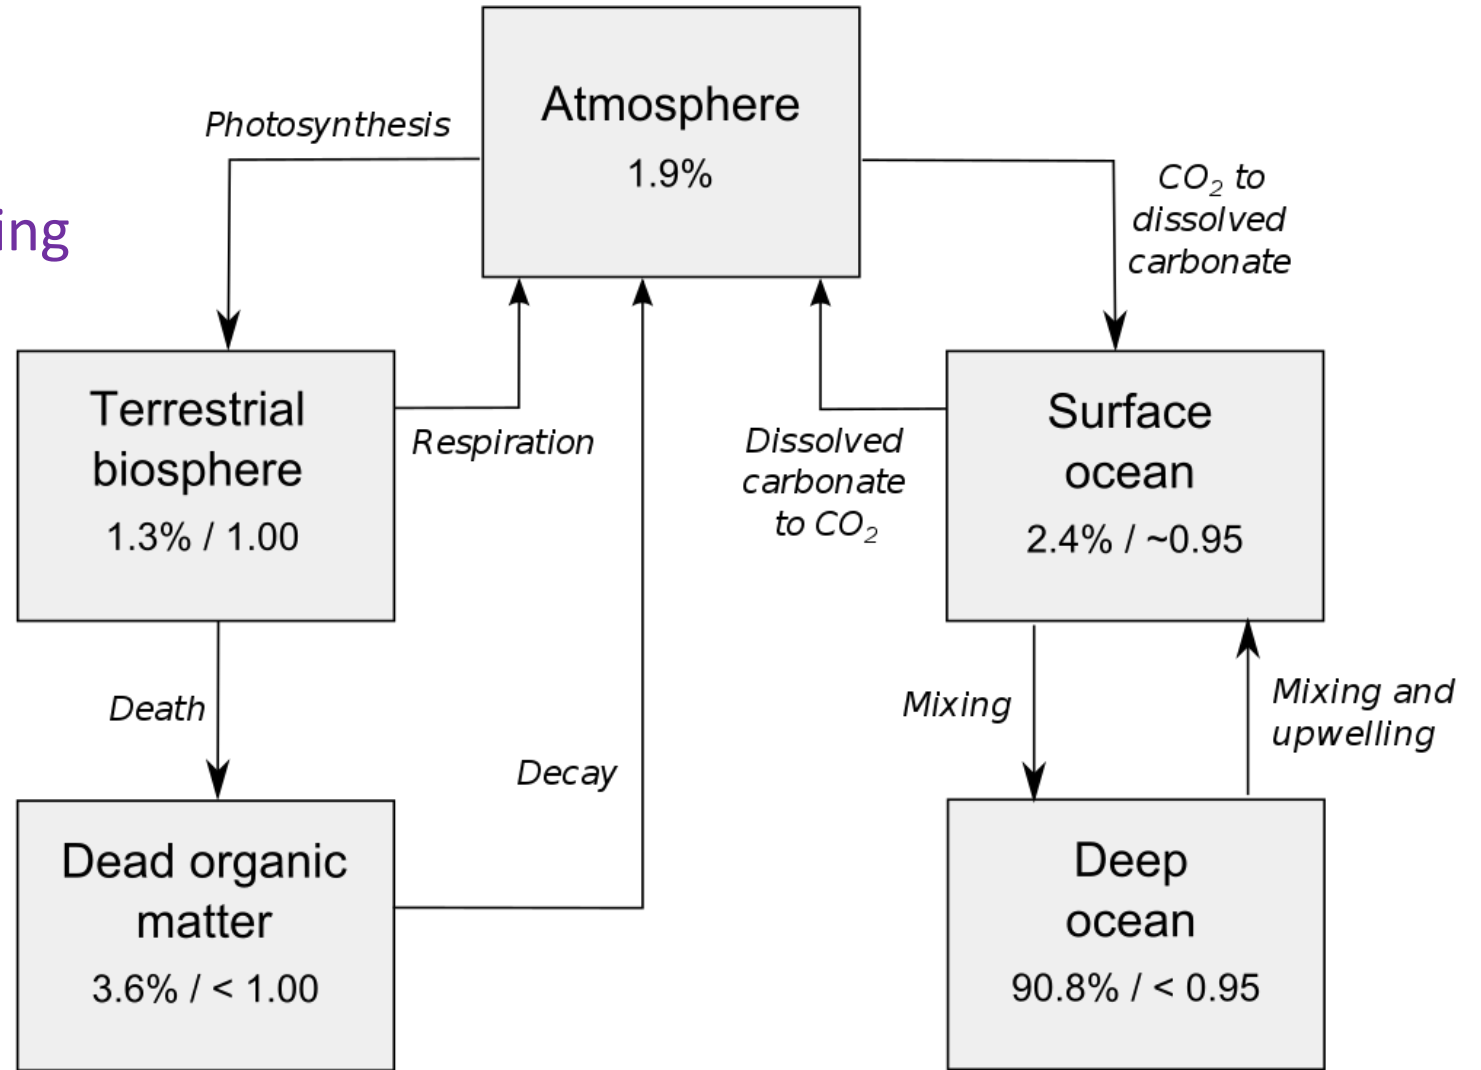

- Activity:
 - Number of disintegrations in a radioactive source is used to measure the intensity of the source
 - Main unit is Becquerel (Bq). 1 Bq is one event per second (typical kBq, MBq, GBq)
- Absorbed dose (exposure for X-rays):
 - The amount of energy coming from a source that is absorbed in a tissue. Used to assess the potential for biochemical changes in specific tissues.
 - Main unit is Gray (Gy). 1 Gy means that one kg of matter absorbed one joule of energy (typical mGy)
- Equivalent or biological dose:
 - Used to assess how much biological damage is expected from the absorbed dose. Different types of radiation have different damaging properties
 - Main unit is Sievert (Sv). 1 Sv equal 1 Gy multiplied by a weighting factor
- Effective dose:
 - Used to assess the potential for long-term effects that might occur in future. Takes into account all the organs in the body, the timespan of irradiation etc.

Exercise-3: How does Radiocarbon dating work?

- Exercise:
 - Explain how the Carbon dating method works

Percentages show the fraction of the total carbon reservoir of each type.
Numbers after slash show ratio of ^{14}C to ^{12}C as fraction of atmospheric ratio.

A model of the nucleus: Liquid drop model (~1935)

- Nucleus ~ uniform density, like an incompressible drop of water
- Strong nuclear force – pairs of nucleons: expect $\sim A^2$, but:
 - Very short ranges: sees only nearest neighbours
 - 'Volume' energy term $\propto A$
 - At surface less neighbours: a negative correction
 - 'Surface tension' term: $\propto A^{2/3}$, (since radius $\propto A^{1/3}$)
- Coulomb repulsion: Long range, all protons see all others. $R \propto A^{1/3}$
 - 'Coulomb term': $\propto Z^2 A^{-1/3}$ (think of sphere of charge density $\propto Q^2/R$)
- Pauli exclusion:
 - Asymmetry term, prefer to fill up low energy states first:
 - 'Pauli term': $\propto (N - Z)^2 / A$ or $(A - 2Z)^2 / A$
- Spin-spin coupling (pairing term), lowers energy if even #p or even #n:
 - $\propto \delta A^{-3/4}$ (empirical) where $\delta = \{-1, 0, 1\}$ if $= \{Z \text{ and } N = \text{even}, A = \text{odd}, Z \text{ and } N = \text{odd}\}$
- Binding energy (semi-empirical):
$$E_B = a_1 A - a_2 A^{2/3} - a_3 \frac{Z^2}{A^{1/3}} - a_4 \frac{(N-Z)^2}{A} + \delta a_5 A^{-3/4}$$
- Bethe-Weizsacker empirical mass formula:
$$M(A, Z) = (A - Z)m_n + Z(m_p) - \frac{E_B}{c^2}$$

See Wikipedia:
Semi-empirical_mass_formula

Volume

 - Asymmetry term, prefer to fill up low energy states first:
 - 'Pauli term': $\propto (N - Z)^2/A$ or $(A - 2Z)^2/A$
- Spin-spin coupling (pairing term), lowers energy if even #p or even #n:
 - $\propto \delta A^{-3/4}$ (empirical) where $\delta = \{-1, 0, 1\}$ if $= \{Z \text{ and } N = \text{even}, A = \text{odd}, Z \text{ and } N = \text{odd}\}$
- Binding energy (semi-empirical):

$$E_B = a_1 A - a_2 A^{2/3} - a_3 \frac{Z^2}{A^{1/3}} - a_4 \frac{(N-Z)^2}{A} + \delta a_5 A^{-3/4}$$
- Bethe-Weizsacker empirical mass formula:

$$M(A, Z) = (A - Z)m_n + Z(m_p) - \frac{E_B}{c^2}$$

See Wikipedia:
Semi-empirical_mass_formula

Values:

$$a_1 \approx 15.6 \text{ MeV}, a_2 \approx 16.8 \text{ MeV},$$

$$a_3 \approx 0.72 \text{ MeV}, a_4 \approx 23.3 \text{ MeV}$$

$$a_5 \approx 34 \text{ MeV}$$

Binding Energy: 'magic numbers'

- Fits quite well
- Cannot explain 'peaks' that occur at 'magic numbers' where the nucleus is strongly bound.
 - N or $Z = 2, 8, 20, 28, 50, 82, 126$
- Double magic nuclei (both N and Z are magic):
 - ${}^4\text{He}$, ${}^{16}\text{O}$, ${}^{40}\text{Ca}$, ${}^{48}\text{Ca}$, ${}^{48}\text{Ni}$, ${}^{208}\text{Pb}$

Nuclear Shell model (1949)

- Similar to the atomic shell model (remember hydrogen atom) for electrons):

- Atomic shells: Energy levels; n, l, s quantum numbers
- Solution of Schrodinger equation (QED)

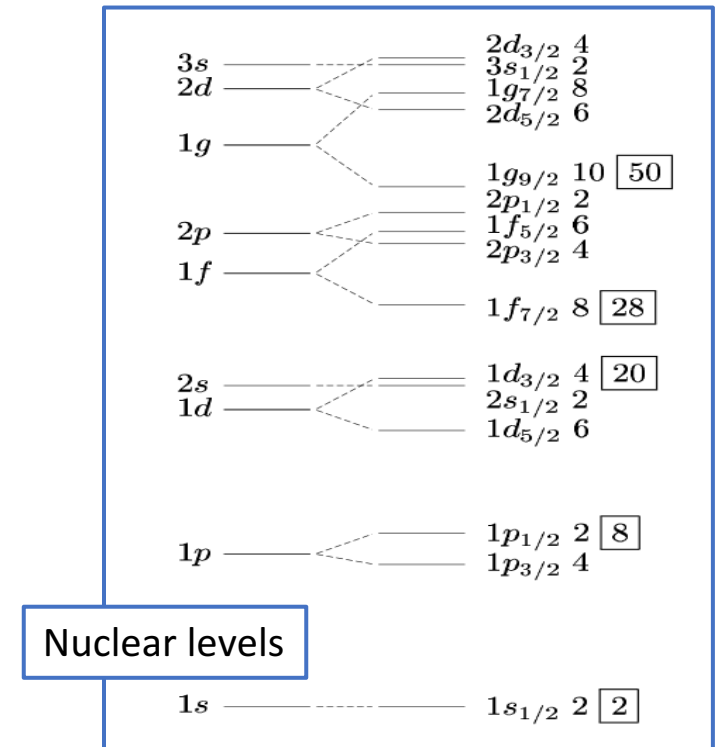

$$\bullet \quad i\hbar \frac{\partial}{\partial t} \psi = -\frac{\hbar^2}{2m} \nabla^2 \psi + V\psi \quad \text{with } V = -\frac{e^2}{4\pi\epsilon_0} \frac{1}{r}$$

- Now strong force: which potential V ?

- Use the nuclear potential
- Try square well, try Harmonic oscillator, $V = \mu\omega^2 r^2 / 2$
Need something inbetween.
- Woods Saxon works well: $V(r) = -\frac{V_0}{1+\exp\left(\frac{r-R}{a}\right)}$
- Spin orbit interaction is stronger than in atom

- Nuclear shells “magic numbers”:

- Count energy levels of shells including spin:
 - $2 \times 1 = 2, 2 \times (1+3) = 8, 2 \times (1+3+6) = 20, \dots$
- Filled shell \rightarrow more tightly bound \rightarrow larger E_B

Nuclear Fission and Fusion

Nuclear Fission

- Heavy elements: less binding energy per nucleon (=more mass)
 - Transition heavy \rightarrow light: free some mass \rightarrow energy ($E = mc^2$)
 - Form high mass unstable isotope: eg. $^{235}_{92}\text{U} + 1 \text{ neutron}$. Reaction:
$$^{236}_{92}\text{U} \rightarrow ^{141}_{56}\text{Ba} + ^{92}_{36}\text{Kr} + 3^1_0\text{n}$$
$$236.045568u \rightarrow 140.914411u + 91.926156u + 3 \times 1.008644u$$
$$\Delta m = 0.18u \Rightarrow E = \Delta m c^2 = 2.68 \times 10^{-11} \text{J} = 168 \text{ MeV}$$
- Note: $^{235}_{92}\text{U}$ occurs as 0.72% natural Uranium
 - To use it as an energy source it must be enriched (centrifuge)
- E_B turned into kinetic energy \rightarrow high temperature \rightarrow steam
 - Nuclear reactors: controlled reaction, moderators for neutron absorption
 - Nuclear bombs: uncontrolled reaction

Nuclear Fusion

- Light elements fuse to free energy (Δm)
- Need to overcome Coulomb barrier in order to fuse together
 - Fuse H or D

- Classically possible to fuse?
 - Would require extremely high kinetic energy \rightarrow unrealistic temperature
 - Sun would not burn!
- Quantum mechanical tunneling helps:
 - Go through the barrier instead of over it
 - Gamow factor

Nuclear Fusion: lab

- Fusion for power: need high energies and densities
 - ITER in France
- $150 \times 10^6 \text{ } ^\circ\text{C}$
- Challenges:
 - keep confined
 - Keep sustained

ITER in 2020

Nuclear Fusion: Universe

See Wikipedia: Nucleosynthesis

- Fusion in stars:
 - Proton-proton chain reaction (sun)
 - CNO catalytic cycle ($m_{star} > 1.3 m_{sun}$)

- How are heavy elements formed in the universe?
 - Colliding neutron stars

Exercise-4: Fission vs Fusion

- a) Calculate the energy released if 1 gram of U-235 splits into La-148 + Br-87.
- b) Calculate the energy released in the fusion process of 0.5 grams of heavy water (D₂O) with 0.5 grams of superheavy water (T₂O), creating He-4 and a neutron. You may neglect the binding energies of the molecules.
- c) Compare the energies released per gram of fuel calculated above. Which would you prefer?

R. Feynman

The classic era

- ~1900: Lord Kelvin on physics:
 - “There is nothing new to be discovered in physics now. All that remain is more and more precise measurements.”
 - Enter Relativity Theory and Quantum Mechanics
- 1896-1897 Becquerel, Röntgen, Marie & Pierre Curie discover radiation
- 1897: J.J Thomson noted cathode rays are quantized particles, charge to mass ratio: discovery of electrons
- 1900: Planck: The blackbody spectrum can be explained by introducing emission of light in *quanta* \hbar
- 1905: Einstein: photo electric effect: light is quantized: photon
 - Scattering behaviour verified in 1923 by Arthur Holly Compton
- 1911: Rutherford: nucleus hydrogen is a proton
- 1932: Chadwick: discovery of the neutron
 - Neutral particle with the mass of a proton

Griffiths §1.1 and §1.2

Black body spectrum: Planck

Photoelectric Effect: Einstein

Mesons 1934 - 1947

Griffiths §1.3

- The nucleus is held together by strong force, mediated by pions or pi-mesons.
- Can we see these pion quanta of mass $\sim 150 \text{ MeV}$?
- In 1937 particles were detected in cosmic rays:
 - Their mass was a bit too light: $m = 105 \text{ MeV}$
 - *They did not interact strongly with nuclei ?!*
- It turned out to be a muon, heavy version of the electron
 - “Who ordered that?": Isaac Rabi
- Particles:
 - Hadrons (p, n), Mesons (π), Leptons (e, μ)

Lepton: Greek “small” or “thin”: small mass, feels no nuclear force
Hadron: Greek “thick”: large mass, feels nuclear interaction
Meson: Greek “middle”: medium mass, feels nuclear interaction

Discovery of the pion - 1947

Griffiths §1.3

- Powell, 1947
 - Go to mountain top
 - Photographic emulsion
- Observes that cosmic rays include muons and pions
 - $m_{\pi} = 140 \text{ MeV}/c^2$
 - $m_{\mu} = 105 \text{ MeV}/c^2$
- A pion can decay into a muon, which can again decay into an electron
- The pion was Yukawa's meson

Antimatter particles 1928 - 1956

Griffiths §1.4

- In 1928 Dirac predicted the existence of antimatter particles, combining relativity theory and quantum mechanics
 - We will learn about Dirac's equation later
- Exercise: convince yourself that Klein-Gordon equation: $E^2 = p^2c^2 + m^2c^4$ is in agreement with the relativistic formulae: $E = \gamma mc^2$ and $p = \gamma mv$
- Dirac: E can have positive and negative solutions:
 - Positive: matter particles (electron)
 - Negative antimatter particles (positron)
- In 1932 the positron was discovered by Anderson

Question: How did he know which direction the particle went?

Antimatter particles 1928 - 1956

- Feynman Stückelberg interpretation of particles (more in lecture 3):
 - The *negative energy* solution of a *particle* corresponds with the *positive energy* solution of an *antiparticle* going backwards in time.

$$\psi_{\pm}(\vec{x}, t) = a_{\pm} e^{\frac{i}{\hbar}(\vec{x}\vec{p} - Et)}$$

- CPT theorem: an antiparticle *is* an anti-particle going backwards in time
- For each particle p there exists a mirror anti-particle \bar{p} in nature.
 - Berkeley Bevatron: discovery anti-proton (1954, Chamberlain, Segré) and discovery anti-neutron (1956, Cork).
 - The antiparticle has the *same mass, lifetime and spin, but opposite internal quantum numbers like charge*.
 - Matter and antimatter have identical interactions. Definition what is what?
- Wheeler: is there only one electron in the entire universe?
- Question: is there also an anti-photon?

Antiparticle and Crossing Symmetry

- Crossing symmetry:

If: $A + B \rightarrow C + D$, then also possible:

$$A \rightarrow \bar{B} + C + D$$

$$A + \bar{C} \rightarrow \bar{B} + D$$

$$\bar{C} + \bar{D} \rightarrow \bar{A} + \bar{B}$$

Limited by energy conservation.

- Example:

Compton scattering = pair annihilation

$$\gamma + e^- \rightarrow \gamma + e^- = e^- + e^+ \rightarrow \gamma + \gamma$$

- General symmetry between matter and antimatter (CPT theorem)

→ *Why is the universe matter dominated?*

→ *Subtle features in the weak interaction!*

Antiparticle and Crossing Symmetry

- Crossing symmetry:

If: $A + B \rightarrow C + D$, then also possible:

$$\gamma + e^- \rightarrow \gamma + e^-$$

Compton scattering

Recoil electron

Target

(2012)

- Example

Compton

$\gamma + e^-$

- Generation

antimatter (CPT theorem)

→ Why is the universe matter dominated?

→ Subtle features in the weak interaction!

$$e^- + e^+ \rightarrow \gamma + \gamma$$

- Nuclear beta decay: $A \rightarrow B + e^-$
 - Exercise: calculate the kinetic energy of the electron.
 - Observed kinetic energy in tritium decay is a *spectrum*
- Niels Bohr was thinking to abandon the law of conservation of energy(!)

- Pauli proposed that an undetected neutral particle was produced
 - Proposed the name neutron
 - Fermi presented beta decay theory, neutrino: $n \rightarrow p + e^- + \bar{\nu}$

Neutrinos 1930 - 1962

- Powell's discovery of muon and pion
 - Pion decay: $\pi \rightarrow \mu + \nu$

Neutrinos 1930 - 1962

- Powell's discovery of muon and pion
 - Pion decay: $\pi \rightarrow \mu + \nu$
- Later discovery of Powell
 - Pion *and* muon decays: $\pi \rightarrow \mu + \nu$ followed by:
 $\mu \rightarrow e + \nu + \bar{\nu}$
- Neutrinos: are they a bookkeeping device or are they real particles?
 - *Very weak* interaction
 - Can penetrate 1000 lightyears thick lead plate
 - What is their mass? $m_\nu \neq 0$?

Observation of neutrinos

- 1955 Cowan and Reines observe “inverse beta decay”
 - Water tank next to Nuclear Reactor
 - Antineutrinos colliding with protons: $\bar{\nu} + p^+ \rightarrow n + e^+$
 - Inverse beta decay
- Are neutrinos their own antiparticles, like photons?
 - From Cowan and Reines and crossing we know that: $\nu + n \rightarrow p^+ + e^-$ must exist
 - Davis and Hamer looked for: $\bar{\nu} + n \rightarrow p^+ + e^-$ It does **not** exist
 - Neutrino is not its own antiparticle. Or is there more going on?
- What distinguishes a neutrino from an anti-neutrino?
 - A nice research topic: “Dirac” neutrinos vs “Majorana” neutrinos

Lepton Number and Lepton Flavor

- 1953, Introduction Lepton number

- Leptons (e^- , μ^- , ν) have quantum number $L = 1$
- Antileptons ($\bar{e} = e^+$, $\bar{\mu} = \mu^+$, $\bar{\nu}$) have quantum number $L = -1$
- Lepton number is conserved in reactions, eg:

$$\begin{array}{ccccccc} \pi^- & \rightarrow & \mu^- & + & \bar{\nu} & & \text{or} & \pi^+ & \rightarrow & \mu^+ & + & \nu \\ L: & 0 & 1 & & -1 & & & 0 & & -1 & & \end{array}$$

- Lepton Flavor: how about: $\mu^- \rightarrow e^- + \gamma$? It is not observed!

- Each lepton ‘family’ has its own lepton number conservation, eg:

$$\begin{array}{cccc} \mu^- & \rightarrow & e^- & + & \bar{\nu}_e & + & \nu_\mu \\ L_\mu: & 1 & 0 & & 0 & & 1 \\ L_e: & 0 & 1 & & -1 & & 0 \end{array}$$

Lepton number is conserved for each type (‘generation’) separately

- Proven in 1962: $\bar{\nu}_\mu + p \rightarrow \mu^+ + n$ was observed,

while: $\bar{\nu}_\mu + p \rightarrow e^+ + n$ was not!

- How did they know? Because these neutrino’s were produced by pion decays into a muon at Brookhaven lab.

Lepton summary 1962 - 1976

	Lepton number	Electron number	Muon number
Leptons			
e^-	1	1	0
ν_e	1	1	0
μ^-	1	0	1
ν_μ	1	0	1
Antileptons			
e^+	-1	-1	0
$\bar{\nu}_e$	-1	-1	0
μ^+	-1	0	-1
$\bar{\nu}_\mu$	-1	0	-1

- Are neutrinos massless? Not exactly → Neutrino oscillations
 - Neutrino's can oscillate to different neutrino type and back! (good research topic)

Strangeness (1947 – 1960)

Griffiths §1.6

- Rochester and Butler observed strange “V-prongs” in cosmic rays:

- Strange: produced copiously, but decay slowly!
 - Abraham Pais: They are produced with the strong force, but they decay with the weak force.

Similarly observed: $\Lambda \rightarrow p^+ \pi^-$

Example of associated strangeness production

Bubble chamber picture of the associated reaction $\pi^- + p \rightarrow K^0 + \Lambda$. Incoming pion is indicated by the arrow. The unseen neutral particles K^0 and Λ are detected by their “ V^0 ” decays: $K^0 \rightarrow \pi^0 + \pi^-$ and $\Lambda \rightarrow \pi^- + p$.

It turns out these strange particles are always produced in pairs.

Strangeness

- Also observed: $K^+ \rightarrow \pi^+ + \pi^+ + \pi^- \rightarrow M_K \sim 500 \text{ MeV}$; it's a meson
- 1952, Brookhaven cosmotron: new strange *baryons*: Σ ($\sim 1.2 \text{ GeV}$), Ξ ($\sim 1.3 \text{ GeV}$)
- In production (strong interaction) conserve *baryon number* as well as *strangeness*

	B:	S:	OK?
$\pi^- + p \rightarrow K^+ + \Sigma^-$	$0 + 1 \rightarrow 0 + 1$	$0 + 0 \rightarrow 1 + -1$	Yes
$\rightarrow K^0 + \Lambda$	$0 + 1 \rightarrow 0 + 1$	$0 + 0 \rightarrow 1 + -1$	Yes
$\rightarrow \pi^+ + \Sigma^-$	$0 + 1 \rightarrow 0 + 1$	$0 + 0 \rightarrow 0 + -1$	No
$\rightarrow K^+ + K^-$	$0 + 1 \rightarrow 0 + 0$	$0 + 0 \rightarrow 1 + -1$	No

- In decay (weak force) *strangeness is not conserved*: long lifetimes
eg. decays: $\Lambda \rightarrow p^+ + \pi^-$; $\Sigma^+ \rightarrow n + \pi^+$
- Electric charge is always conserved!

The Particle Zoo and the Eightfold Way

Griffiths §1.7

- So many particles! *“The finder of a new elementary particle should be punished by a 10,000 \$ fine!”* - Willis Lamb, 1955.
- Gell-Mann (1961): Make a classification a la Periodic Table

The Particle Zoo and the Eightfold Way

- So many particles! *“The finder of a new elementary particle should be punished by a 10,000 \$ fine!”* - Willis Lamb, 1955.
- Gell-Mann (1961): Make a classification a la Periodic Table
- For heavier baryon particles (spin- $\frac{3}{2}$) there is a decuplet
 - The reason that spin- $\frac{1}{2}$ baryons form an octet and spin- $\frac{3}{2}$ a decuplet is far from trivial.
- The Ω particle was not known yet:
 - Mass and lifetime was predicted
 - Observed in 1964
- Octets and decuplets suggest an underlying structure! – quarks!

Discovery of the Omega particle

Decay in three steps,
each with $\Delta S = -1$

The Quark Model (1964)

Griffiths §1.8

- Gell-Mann and Zweig independently proposed that elementary particles are composed of spine- $\frac{1}{2}$ *quarks: up, down, strange*:

- Baryons: particle consisting of 3 quarks or antiquarks ($q q q$) or ($\bar{q} \bar{q} \bar{q}$)
 - Proton= uud , neutron= udd , etc
- Mesons: particles consisting of 1 quark and 1 anti-quarks: ($q \bar{q}$)
 - Pions: $\pi^+ = u\bar{d}$, $\pi^0 = u\bar{u}+d\bar{d}$, $\pi^- = d\bar{u}$
 - Kaons: $K^+ = u\bar{s}$, etc

Explains “elementary particles” as quark combinations, spin, strangeness etc.

The Quark Model (1964)

- Gell-Mann and Zweig independently proposed that elementary particles are composed of spine- $\frac{1}{2}$ *quarks: up, down, strange*:

The meson nonet			
$q\bar{q}$	Q	S	Meson
$u\bar{u}$	0	0	π^0
$u\bar{d}$	1	0	π^+
$d\bar{u}$	-1	0	π^-
$d\bar{d}$	0	0	η
$u\bar{s}$	1	1	K^+
$d\bar{s}$	0	1	K^0
$s\bar{u}$	-1	-1	K^-
$s\bar{d}$	0	-1	\bar{K}^0
$s\bar{s}$	0	0	??

The baryon decuplet			
qqq	Q	S	Baryon
uuu	2	0	Δ^{++}
uud	1	0	Δ^+
udd	0	0	Δ^0
ddd	-1	0	Δ^-
uus	1	-1	Σ^{*+}
uds	0	-1	Σ^{*0}
dds	-1	-1	Σ^{*-}
uss	0	-2	Ξ^{*0}
dss	-1	-2	Ξ^{*-}
sss	-1	-3	Ω^-

- Complications: η' singlet, baryon octet:
 - Spin and (anti-)symmetrization of wave functions!*

Complications

- The spin- $\frac{1}{2}$ octet is like the spin- $\frac{3}{2}$ decuplet with the corners missing.
- Wave function has:
 - 3 identical quarks ($u u u$), ($d d d$), or ($s s s$)
 - 3 identical spin directions of quarks: $\uparrow\uparrow\uparrow$ or $\downarrow\downarrow\downarrow$

Desperate Measures

- A quantum mechanical problem: check Δ^{++} :
 - Wave function has:
 - 3 identical quarks ($u u u$), ($d d d$), or ($s s s$)
 - 3 identical spin directions of quarks: $\uparrow\uparrow\uparrow$ or $\downarrow\downarrow\downarrow$
 - Not allowed by Pauli-exclusion principle:
 - This wave function is symmetric under particle exchange
 - *Identical* spin- $\frac{1}{2}$ particles must have an asymmetric wave function under exchange of the particles

- Quarks differ by having an additional quantum number: **color**
 - A quark can have quantum number: “red”, “green”, “blue”
 - An anti-quark can carry quantum number: “anti-red”, “anti-green”, “anti-blue”
- All physical particles must be colorless (“confinement”):
 - baryons $\rightarrow r g b$, mesons $\rightarrow r \bar{r}$, $g \bar{g}$, or $b \bar{b}$

No free quarks in nature!

How to make a mental picture of a proton?

- Looking from "afar" there are three colored quarks: red, green, blue
- Zooming in it becomes a quantum foam of particles + antiparticles + force particles (gluons)

Deep Inelastic Scattering (“DIS”)

- Indeed individual quarks have never been observed.
 - Do they actually exist or are they just a mathematical bookkeeping tool?
- ~1970 SLAC: “DIS”
 - Proton substructure is seen similar to Rutherford scattering
- Quarks are real and they carry an additional quantum number which can have three values
 - “Color” is just a name

Research:

what is the principle behind confinement, ie. being colorless?

The November Revolution: 1974 - 1983

Griffiths §1.9

- Fundamental particles:
 - Why 4 Leptons: (e, ν_e) (μ, ν_μ) and 3 Quarks : (u, d, s) ?
 - 1974 Two groups discover a new particle: Ting at BNL (“ J ”) and Richter at SLAC (“ ψ ”)
 - J/ψ particle is special: very heavy $M \sim 3000 \text{ MeV}$, long lifetime $\tau \sim 1000 \times$ longer than heavy hadrons
→ new meson consisting of heavy charm quarks: $c\bar{c}$ → Enter: **charm** quantum number
- Existence of charm also solved the Glashow, Iliopoulos, Maiani (GIM) puzzle.
 - It explained why the K_L particle had a very long lifetime
- Other new particles were discovered soon afterwards
 - Mesons: $D^0 (c\bar{u})$, $D^+ (c\bar{d})$, $D_s^+ (c\bar{s})$, ...
 - Baryons: $\Sigma_c (uuc)$, $\Lambda_c (udc)$, $\Xi_c (usc)$, $\Omega_c (ssc)$, ...
- Similar to “strangeness”, “charm” is conserved in production (strong force), and violated in (weak force) decay

The November Revolution: 1974 - 1983

- 1974 Discovery of charm brings Lepton-Quark symmetry:
 - (ν_e, e) (ν_μ, μ) and (u, d) (c, s)
- 1975 Discovery of the τ - lepton breaks symmetry again
 - Also a corresponding ν_τ neutrino
- 1977 Discovery Υ ($b\bar{b}$) particle, consisting of *bottom* or *beauty* quarks
 - Baryons: 1980: $\Lambda_b^0(udb)$, 2006: $\Sigma_b^+(uub)$, 2007: $\Xi_b^-(dsb)$,
 - Mesons: 1983: $B^0(\bar{b}d)$, $B^-(b\bar{u})$, later also: $B_s^0(\bar{b}s)$, $B_c^+(\bar{b}c)$
 - First $B_c^+ \rightarrow B_s^0$ weak decay observed by J.A. de Vries *et al.*
- Terminology: upness, downness, strangeness, charm, beauty = “*Flavour*”
 - Quarks have *charge*, *flavor* and *color* quantum numbers
- Now 6 leptons and 5 quarks?
 - (ν_e, e) (ν_μ, μ) (ν_τ, τ) and (u, d) (c, s) (b, \dots)

Top quark

- Discovered at Fermilab 1995
 - $p + \bar{p} \rightarrow t + \bar{t}$
 - Top decay immediately and form so-called *jets*

- Top quark:
 - $m_t = 176 \text{ GeV}$, very heavy quark
 - $\tau_t = 5 \times 10^{-25} \text{ s}$, extremely short
 - No bound states with top quark exist

Standard Model of Elementary Particles

three generations of matter (elementary fermions)			three generations of antimatter (elementary antifermions)			interactions / force carriers (elementary bosons)	
	I	II	III	I	II	III

Current Fundamental Questions in Particle physics

- Why are there three generations of particles?
- Why are the masses of the particles what they are?
- Why is there no antimatter in our universe?
- Why is the charge of the electron exactly opposite to that of the proton?
Or: why is the sum of the charge of leptons + quarks exactly equal to zero?
- Is a neutrino its own anti-particle?
- Can all forces be described in a single theory? Unification
- Are quarks and leptons truly fundamental
- What is the source of dark matter?
- What is the source of dark energy?

- In particle physics we make often use of natural units
 - Very confusing at first but very convenient when you are used to it (“sloppy”)
Set $c = 2.998 \times 10^8 \text{ m/s} \equiv 1$ and $\hbar = 1.055 \times 10^{-34} \text{ Js} \equiv 1$
(Just leave them out and put them back at very end of any calculation)
 - Consequence: there is only one basic unit for length, time, mass and energy: GeV
- Exercise: derive the numbers on the conversion table on the next page

Natural Units: conversion table

quantity	symbol in natural units	equivalent symbol in ordinary units
space	x	$x/\hbar c$
time	t	t/\hbar
mass	m	mc^2
momentum	p	pc
energy	E	E
positron charge	e	$e\sqrt{\hbar c/\epsilon_0}$

Conversion of basic quantities between natural and ordinary units.

quantity	conversion factor	natural unit	normal unit
mass	$1\text{ kg} = 5.61 \times 10^{26}\text{ GeV}$	GeV	GeV/c^2
length	$1\text{ m} = 5.07 \times 10^{15}\text{ GeV}^{-1}$	GeV^{-1}	$\hbar c/\text{GeV}$
time	$1\text{ s} = 1.52 \times 10^{24}\text{ GeV}^{-1}$	GeV^{-1}	\hbar/GeV

Conversion factors from natural units to ordinary units.

Exercise-6 : the quark model; wave function of hadrons

- a) Quarks are fermions with spin $1/2$. Show that the spin of a meson (2 quarks) can be either a triplet of spin 1 or a singlet of spin 0.
- Hint: use the “Clebsch-Gordon” coefficients in adding quantum numbers. In group theory this is often represented as the product of two doublets leads to the sum of a triplet and a singlet: $2 \otimes 2 = 3 \oplus 1$ or, in terms of quantum numbers: $1/2 \otimes 1/2 = 1 \oplus 0$.
- b) Show that for baryon spin states we can write: $1/2 \otimes 1/2 \otimes 1/2 = 3/2 \oplus 1/2 \oplus 1/2$ or equivalently $2 \otimes 2 \otimes 2 = 4 \oplus 2 \oplus 2$
- c) Let us restrict ourselves to two quark flavours: u and d . We introduce a new quantum number, called *isospin* in complete analogy with spin, and we refer to the u -quark as the isospin $+1/2$ component and the d -quark to the isospin $-1/2$ component (or u =isospin “up” and d =isospin “down”).
- What are the possible isospin values for the resulting baryon?
- d) Optional for die-hards! The Δ^{++} particle is in the lowest angular momentum state ($L = 0$) and has spin $J_3 = 3/2$ and isospin $I_3 = 3/2$. The overall wavefunction ($L \Rightarrow$ space-part, $S \Rightarrow$ spin-part, $I \Rightarrow$ isospin-part) must be anti-symmetric under exchange of any of the quarks. The symmetry of the space, spin and isospin part has a consequence for the required symmetry of the Color part of the wave function.
- Write down the color part of the wave-function taking into account that the particle is color neutral.
